

Screenshots of the report:

Playwright accessibility report confirms and validates all the manual and semi-manual findings I have found using WAVE and Screen Reader.

The report shows critical and serious failures against *WCAG 2.1 Level AA* standards. While the site is visually great and modern, the code architecture underneath it lacks the necessary accessible names that are required for navigation via keyboard and screen reader. Report shows several blockers for users flaw, for example search button failure, which lacks a proper accessible name in the code. It also shows that the website has disabled user zooming, which is violating the standards.

The automated report basically shows technical proof for the issues I found manually, and adds more of a technical description to it.

For example:

- **Silent interactive elements**

Manual: I found some buttons that were empty, and when using Screen Reader were announced without a specific label.

Automated: The report confirms that the *.header__search > button* and *.header__logo* have no inner text or aria-label.

- Missing Form Label

Manual: With WAVE I found "Missing Form Label" even though you can hear "Search" via the placeholder while using the Screen Reader.

Automated: The report confirms that the input lacks a *<label>* or *aria-label*.

Conclusion:

The website currently is not fully accessible for users who rely only on keyboard navigation and Screen Reader. Automated and manual tests both showed the same errors that indicate the systematic issue in the written code. To improve the website and make it more accessible to users, the developers team should prioritize accessible namings by adding the aria-labels. By adding it to the header and the footer of the page, a lot of the found bugs will be resolved.
